Média Volátil. Fendas Odds Explicou House Edge, Vitória Probabilidade
e Pagamentos n tecopedia : guia de jogo
The "21 + 3" blackjack side bet is based on examining the player's two cards and the
dealer's up-card. If the three cards form a flush, straight, three-of-a-kind or
straight flush, the player wins. In the original version, the payout for each of these
was 9-to-1. With this pay table, the game has a house edge of 3.2386%. Recently, new
 pay tables have been introduced that have higher house edges and greater
volatility.
The point of attack I considered is to target flushes. Any strong imbalance
in the suits favors the player. For example, consider a situation where there are 40
 cards, 10 of each suit. Without going into the math, the number of ways of making a
three-card flush is 480. Now, take those same 40 cards, and assume they are distributed
15, 10, 10, 5. Then the number of three-card flushes is 705. The more unbalanced the
distribution of suits, the more the edge swings towards the player.
To make use of
this, it is necessary to keep track of the number of cards in each suit that remain in
 the shoe. This can be accomplished by a team of counters, each keeping track of one of
the suits (or by a mentally gifted solo counter). The counters then compute the
difference between the most abundant and least abundant suits. This difference is then
turned into a true count, and if that true count is sufficiently large, the player has
 an edge.
I created a simulation to model using this system on a six-deck shoe game
dealt to 52 cards and simulated one hundred million (100,000,000) shoes. This work
showed that a counter can gain an edge on approximately 3.5% of the hands dealt (1.75
hands per shoe). The counter should make the 21+3 wager whenever the true count is 8 or
higher. The average edge when the wager is made will be just over 5%. If the table
limit isR$25, then a counter playing heads-up can earn aboutR$2.20 per shoe. The new
pay tables were not evaluated.
As an experiment, I shuffled one hundred thousand
(100,000) shoes and computed the edge at the point when there were 100 cards remaining
in the shoe. The result of this simulation was an average house edge of 3.247%, which
is close to the theoretical value of 3.239%. More interesting was that the standard

deviation of the house edge was 3.57%. It follows that a player edge is 0.910 standard deviations above the mean. Therefore, the player will have an edge on about 18.14% of the shoes at that point. The trick is knowing which ones. My simulation gave a maximum player edge of 23.71% and a maximum house edge of 13.55%.
There are two reasons that
APs will not target 21+3 with this system. The first is its complexity, the second is the low return. However, there is another approach that may be significantly stronger.Consider a shuffle tracking approach where a slug of cards is identified that is either deficient in one suit or abundant in one suit. In this case, by tracking that slug through a weak shuffle, the AP will have a good opportunity. My knowledge of shuffle tracking is minimal. I cannot say if this is an approach that has been used in practice. Finally, I have not considered if the new pay tables have a similar vulnerability to the 9-to-1 pay table.
